Abstract

We investigate the dynamical gauge-Higgs unification in the Randall-Sundrum (RS) space-time. We study the dynamical gauge-Higgs unification in the $SU(2)$ gauge theory with a bulk fermion in the RS space-time. We evaluate the contribution from fermion loop to the one-loop effective potential with respect to the Wilson-line phase, and study the dynamical gauge symmetry breaking. We also apply this mechanism of the gauge symmetry breaking to the electroweak gauge-Higgs unification in the RS space-time. Especially we numerically studied a $SU(3)_w$ gauge model as a toy model of electroweak gauge-Higgs unification in the RS space-time. We introduce an adjoint fermion into the model to break the gauge symmetry and to obtain the $U(1)_{\rm em}$ electromagnetic symmetry. We found that in this model the ratio of Z-boson mass to W-boson varies with respect to the Wilson-line phase even at the tree level. We also propose a dynamical mechanism of tuning the ratio m_Z/m_W to the experimental value $91.2\text{GeV}/80.4\text{GeV} = 1.13$ by introducing bulk scalars or bulk fermions with twisted boundary conditions. In these models the Higgs can vary in mass between zero and $290\,\text{GeV}$.

I. INTRODUCTION

The standard model has been in good agreement with current experimental data. The origin of the electroweak symmetry breaking, however, has not yet confirmed. As an alternative to the Higgs mechanism, the electroweak gauge-Higgs unification (EWGHU) has been considered for many years (for early works, see [1, 2, 3]). In the EWGHU, the Higgs field is regarded as an extra-dimensional component of the gauge field in higher-dimensional space-time. If the gauge group is non-Abelian and the spatial extra dimension is multiply-connected, then the gauge symmetry can be broken by the non-Abelian Wilson line phase in the extra dimension (i.e., broken through the Hosotani mechanism) [4, 5]. Furthermore, such Wilson line phases can be dynamically induced [4, 6, 7]. One can define the effective potential with respect to the Wilson-line phases. The Wilson-line phases are dynamically selected as the phases that minimize the effective potential. This dynamical mechanism of the gauge-symmetry breaking by Wilson-line phases is referred as the dynamical gauge-Higgs unification. In the dynamical gauge-Higgs unification, both of the size of the mass and the magnitudes of the effective potential are almost of the order of size of the extra dimensions. Therefore, since possibilities of the TeV-scale extra dimensions are pointed out [8, 9], the EWGHU scenario has been extensively studied in the context of the dynamical gauge-Higgs unification [10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27].

However, in the construction of a realistic model of the EWGHU in the flat extra dimension, we encounter several obstacles. To see this, let us consider the models with "flat extra dimensions". Here models with flat extra dimensions are models such that (i) Extra dimensional space has vanishing curvature (e.g., a circle S^1 or n-torus T^n). (ii) The metric of the spacetime is assumed to be "factorizable", in other words, the metric of the four-dimensional space-time can be independent of coordinates of extra dimensions. The obstacles we will see in these models are as follows.

(a) In models of the EWGHU with dynamical gauge-Higgs unification in a flat extra dimension, we obtain too small Higgs mass. In [17] the Higgs mass m_h is estimated to be $m_h = \mathcal{O}(m_W \sqrt{\alpha_W})$, where $\alpha_W \equiv g_4^2/4\pi$ with the four-dimensional (4D) weak coupling g_4. With $m_W = 80.4\,\mathrm{GeV}$ and $\alpha_W = 0.032$, we obtain $m_h = \mathcal{O}(10)\,\mathrm{GeV}$, which contradicts the observation.[1]

(b) In models of the EWGHU in the flat extra dimension, the mass of the quarks and leptons tend to be universal and the mixing matrix of quarks to be diagonal, because the gauge coupling constant yields the "Yukawa couplings" of fermions to the Higgs in the gauge-Higgs unification. Therefore, it needs some other mechanisms to induce large mass hierarchy and mixings among fermions.[2]

(c) In the models in the flat extra dimension, one of the simplest way to give different masses to fermions is to assign the different bulk mass term to each fermion. Then, in the EWGHU the mass of the lowest Kaluza-Klein (KK) mode of such a bulk fermion is estimated to be $\sqrt{\theta^2/R^2+m_f^2}$, with the Wilson line phase θ, compactification radius R and bulk mass of the fermion m_f. Thus, a fermion with larger (smaller) bulk mass can be heavier (lighter) in the four dimensional effective theory. Since the effective potential decrease in size with increasing the bulk mass of the fermion [10], it lead us to an odd conclusion: *a light fermion (e.g., up-,down-quark or electron) has large contribution to the effective potential of the Higgs.* The low energy dynamics of the EWGHU in the flat extra dimension looks very different from 4D models of the electroweak symmetry breaking by the Coleman-Weinberg (CW) mechanism [28].

In recent years, models of electroweak gauge-Higgs unification in the Randall-Sundrum (RS) space-time [29] have been extensively studied [30, 31, 32, 33, 34, 35, 36, 37]. We first summarize the merits of the dynamical gauge-Higgs unification in the RS space-time. They are

(A) The hierarchy between electroweak and a larger scale (e.g., the Planck scale) are explained by the nature of the RS space-time [29][3], whereas the quadratic divergence of the Higgs mass is absent due to the higher-dimensional gauge symmetry [4, 10, 21].

(B) The extra dimension of the RS has the orbifold topology S^1/Z_2. On such space-time, we can naturally obtain the chiral structure of fermions by boundary conditions at the fixed points. Z_2 projection also yields the Higgs field in the fundamental representation of $SU(2)_w$ from the gauge field in the adjoint representation of a gauge group which includes the $SU(2)_w \times U(1)$.

---

[1] Ways of pushing up the Higgs mass by fine-tuning of the Wilson-line phase are studied in [22].

[2] Some ways to obtain the Yukawa hierarchy in the gauge-Higgs unification are discussed in [19, 26].

[3] Attempts to obtain the large hierarchy within the framework of the flat extra dimension are seen in [22, 23].

(C) In the RS space-time, we can obtain large mass differences among fermions by tuning bulk mass parameters of fermions of order of unity [38]. In the same way we can obtain large mass hierarchy among fermions in the EWGHU in the RS space-time [34].

(D) The mass of the Higgs will be lifted up to a few hundred GeV when we consider the dynamical gauge-Higgs unification in the RS space-time [33].

(E) When we implement the standard model in the RS space-time, the Higgs field (i.e., the 5th-dimensional component of the gauge field) is naturally localized on the TeV brane. We note that such a localization of the Higgs on the TeV brane is usually required in the context of the 5D extension of the standard model in the RS space-time [39, 40, 41].

The dynamical gauge-Higgs unification in the Randall-Sundrum space-time is first considered in [30] and effective potential by fermion without bulk mass is evaluated in it. An appropriate form of the background gauge in the RS space-time and the calculation of the effective potential from gauge-ghost loop is studied in [31]. The phenomenological studies of the EWGHU in the RS space-time are seen in [32, 33, 34, 35]. We note that there are series of works [36], based on the AdS/CFT dual or "holographic" picture [42]. The Wilson-line dynamics in the warped extra dimension has also been studied in [37] by means of the dimensional deconstruction [43].

In the present paper we investigate the dynamical gauge-Higgs unification in the Randall-Sundrum space-time. The aim of the present paper is the following threefold. First, we evaluate the effective potential of Wilson line and discuss the gauge symmetry breaking by the dynamical gauge-Higgs unification and to evaluate the mass of the Higgs field. Especially we are interested in the one-loop effective potential for the loop of fermion with a bulk mass term. Second, we make clear the relation between the fermion mass spectrum and the effective potential in this model. In the case of warped extra dimension, the lowest KK mass of the fermion decreases in size with increasing absolute value of the bulk mass. Therefore we expect that in the RS space-time, a heavy fermion in the 4D effective theory will have large contribution to the effective potential and a light one has small contribution, as we have seen in the CW mechanism. We will demonstrate it is true. Third, we use the dynamical gauge-Higgs unification in the RS space-time to construct a model of the EWGHU with realistic mass spectrum of fermions and a Higgs potential.

The present paper is organized as follows. In Section II, we study the $SU(2)$ gauge model in the RS space-time and evaluate the one-loop effective potentials from the fermion loop and see how the effective potential and the gauge symmetry depends on the bulk muss term of the fermion. In Section III, as an application of the dynamical gauge-Higgs unification in the RS space-time, we reconsider the $SU(3)_w$ gauge model as a toy model of EWGHU in the warped extra dimension. Section IV is devoted to the summary and comments. In Appendix A Approximation formulas of low-energy mass spectrum of fermions are collected.

II. DYNAMICAL GAUGE-HIGGS UNIFICATION IN THE RS SPACE-TIME

We consider the gauge theory in the the RS two-brane model [29]. The RS space-time is a slice of five-dimensional anti-de Sitter space-time AdS_5, and the metric of the RS space-time can be written as

$$ds^2 = G_{MN} dX^M dX^N = e^{-2\sigma(y)} \eta_{\mu\nu} dx^\mu dx^\nu - dy^2, \tag{1}$$

where the five-dimensional coordinates are $X^M = (X^\mu = x^\mu, X^4 \equiv y)$ $(M, N = 0, 1, 2, 3, 4$ and $\mu, \nu = 0, 1, 2, 3)$. $\eta_{\mu\nu}$ is the 4-dimensional metric and $\eta_{\mu\nu} = \mathrm{diag}(+1, -1, -1, -1)$. We assume that the function $\sigma(y)$ has the periodicity $\sigma(y + 2\pi R) = \sigma(y)$ and the reflection symmetry at $\sigma(y_i + y) = \sigma(y_i - y)$ $(i = 0, 1)$ with $y = y_0 \equiv 0$ and $y = y_1 \equiv \pi R$, where R is the compactification radius. In the present paper we assume that R is already fixed by some mechanisms (e.g. Goldberger-Wise mechanism [44]). For $-\pi R \leq y \leq \pi R$, we write $\sigma(y) = k|y|$, where k is referred as the curvature of the AdS_5. Two boundaries $y = y_0$ and $y = y_1$ are referred as “Planck brane” and “TeV brane”, respectively.

We consider a $SU(2)$ gauge theory in this space-time. We also include a Dirac fermion Ψ in the fundamental representation, or Λ in the adjoint representation. The action of the gauge field and the fermion in the bulk space-time can be given by $S_{\text{gauge}} + S_{\Psi(\Lambda)}$, where

$S_{\rm gauge}$ and S_ψ, $(\psi=\Psi,\Lambda)$ are given by

$$
\begin{aligned}
S_{\rm gauge} &= -\int d^4x \int_{-\pi R}^{\pi R} dy\sqrt{|G|}\left[\frac{1}{4}g^{MN}g^{RS}F_{MR}F_{NS}+\mathcal{L}_{\rm gf}+\mathcal{L}_{\rm ghost}\right], && (2)\\
S_\psi &= \int d^4x \int_{-\pi R}^{\pi R} dy|E|\left\{i\bar\psi E^M{}_m\gamma^m D_M\Psi - kc_\psi\epsilon(y)\bar\psi\psi\right\}, && (3)
\end{aligned}
$$

where F_{MN} is the field strength :$F_{MN}=\partial_M A_M-\partial_N A_M-ig[A_M,A_N]$ and A_M is the gauge field. $\mathcal{L}_{\rm gf}$ and $\mathcal{L}_{\rm ghost}$ are the gauge-fixing and the Faddeev-Popov Lagrangian, respectively. The five dimensional γ-matrices γ^m are defined by $\{\gamma_m,\gamma_n\}=2{\rm diag}(+1,-1,-1,-1,-1)$ (Small Latin indices m,n represent Lorentz indices and $m,n=0,1,2,3,4$), and $\gamma^4=-\gamma_4=-i\gamma_5$. $E^M{}_m$ is an inverse of the fünfbein. $|G|$ and $|E|$ are absolute values of determinants of the metric tensor and the fünfbein, respectively and $|E|=\sqrt{|G|}$ is satisfied. c_Ψ and c_Λ are dimensionless bulk mass parameters for Ψ and Λ, respectively. $\epsilon(y)$ is the sign function: $\epsilon(y)=+1(-1)$ for $y>0$ $(y<0)$. We decompose a field $\Phi_{\rm ad}$ in the adjoint representation and $\Phi_{\rm fd}$ in the fundamental representation into $\Phi_{\rm ad}=\sum_{a=1}^3\sigma_i\Phi_{\rm ad}^{(a)}/2$ and $\Phi_{\rm fd}=(\Phi_{\rm fd}^{(i=1)},\Phi_{\rm fd}^{(i=2)})^T$ (σ_i is the Pauli matrices), respectively.

As a gauge fixing, we choose the background gauge. We separate the gauge field into background A_M^c and quantum fluctuation A_M^q: $A_M=A_M^c+A_M^q$. In the background gauge we write covariant derivatives of the gauge field, fermions in the fundamental and adjoint representation as

$$
\begin{aligned}
D_M^c A_N^q &= \partial_M A_N^q - ig\left[A_M^c,A_N^q\right], && (4)\\
D_M^c\Lambda &= \partial_M+\frac{1}{8}\omega_M^{mn}\left[\gamma_m,\gamma_n\right]-ig\left[A_M^c,\Lambda\right], && (5)\\
D_M^c\Psi &= \partial_M+\frac{1}{8}\omega_M^{mn}\left[\gamma_m,\gamma_n\right]-igA_M^c\Psi, && (6)
\end{aligned}
$$

where ω_M is the spin connection and $\omega_\mu^{n4}=-\omega_\mu^{4n}=-\sigma' e^{-\sigma}\delta_\mu^n$ $(n=0,1,2,3)$, and other components vanish. We expect only y-component of the gauge field can have non-vanishing vacuum expectation value(VEV), i.e., $A_M^c=\delta_M^y\langle A_y\rangle$. By choosing appropriate gauge fixing term [31] and corresponding ghost term in the action, we obtain the quadratic action of A_M^q and the ghost field ω :

$$
S_{\rm g} = -\int d^4x\int dy\,{\rm tr}\left[A^{q\mu}(\Box-\mathcal{D}^2)A_\mu^q+e^{-2\sigma}A_y^q(\Box-D_y^cD_y^ce^{-2\sigma})A_y^q+e^{-2\sigma}\bar\omega(\Box-\mathcal{D}^2)\omega\right] \quad (7)
$$

where $\Box\equiv\eta^{\bar m\bar n}\partial_{\bar m}\partial_{\bar n}$ $(\bar m,\bar n=0,1,2,3)$ and $\mathcal{D}^2\equiv D_y^c e^{-2\sigma}D_y^c$, respectively. For later use, we introduce a new coordinate z, which is defined by $z\equiv e^{\sigma(y)}$ $(0\le y\le\pi R)$. With this coordinate, equations of motion for gauge fields A^q_μ, A^q_z ($A_z = A_y/kz$) and fermionic fields $\psi_{L,R} = \Lambda_{L,R}$, $\Psi_{L,R}$ are given by

$$\begin{aligned} \Box A^q_\mu - k^2 z D^c_z \frac{1}{z} D^c_z A^q_\mu &= 0, && (8) \\ \Box A^q_z - k^2 z D^c_z z D^c_z \frac{1}{z} A^q_z &= 0, && (9) \\ \left\{ \not{\partial} - k\left(\frac{c_\psi}{z} + \gamma_5 D^c_z \right) \right\} e^{-2\sigma}\psi &= 0, && (10) \end{aligned}$$

where $\not{\partial} = \eta^{\bar{m}\bar{n}}\gamma_{\bar{m}}\partial_{\bar{n}}$. Gauge fields $A^{(a)}_M = (A^{(a)}_\mu, A^{(a)}_z/z)$ and fundamental (adjoint) fermions $\psi^I_{L,R} = \Psi^{(i)}_{L,R}$ $(\Lambda^{(a)}_{L,R})$ are decomposed into their Kaluza-Klein modes:

$$\begin{aligned} A^{(a)}_M(x,z) &= \sum_n f^{(a)}_{A_M,n}(z) A^{(a)}_{M,n}, && (11) \\ \psi^I_{L|R}(x,z) &= e^{2\sigma} \sum_n f^I_{L|R,n}(z) \psi^I_{L|R,n}(x). && (12) \end{aligned}$$

Here the left-(right-)handed fermions $\psi_{L(R)}$ are defined by $\psi_{L(R)} = [1 - (+)\gamma_5/2]\psi$. When $\langle A_z \rangle$ vanishes, or when an adjoint field $\Phi^{(a)}_{\rm ad} = A^{q(a)}_M, \Lambda^{(a)}$ commute with the VEV of gauge field: $[\langle A^c_z \rangle, \Phi^{(a)}_M] = 0$, we can simplify Eqs. (8), (9), (10), and we obtain wave equations for KK-mode functions as

$$\begin{aligned} k^2 z \frac{d}{dz}\frac{1}{z}\frac{d}{dz} f^{(a)}_{A\mu,n}(z) &= -(m^{(a)}_{A\mu,n})^2 f^{(a)}_{A\mu,n}(z) && (13) \\ k^2 \frac{1}{z}\frac{d}{dz} z \frac{d}{dz} \frac{f^{(a)}_{Az,n}(z)}{z} &= -(m^{(a)}_{Az,n})^2 \frac{f^{(a)}_{Az,n}(z)}{z} && (14) \\ k\left(\frac{c}{z} + \frac{d}{dz} \right) f^I_{\psi_R,n}(z) &= m^I_{\psi,n} f^I_{\psi_L,n}(z), && (15) \\ k\left(\frac{c}{z} - \frac{d}{dz} \right) f^I_{\psi_L,n}(z) &= m^I_{\psi,n} f^I_{\psi_R,n}(z). && (16) \end{aligned}$$

For a field Φ we obtain non-zero mode ($m_\Phi \neq 0$) solutions for (13), (14), (15), (16) into the form of

$$f_\Phi(z) = z^{s_\Phi}\left[A_\Phi J_{\alpha_\Phi}(\hat{m}_\Phi z) + B_\Phi Y_{\alpha_\Phi}(\hat{m}_\Phi z) \right], \tag{17}$$

with $s_\Phi = \{1, 1, \frac{1}{2}\}$, $\alpha_\Phi = \{1, 0, \frac{1}{2} \pm c_\psi\}$, and $\hat{m}_\Phi \equiv m_\Phi/k$, for $\Phi = \{A_\mu, A_z, \psi_{R/L}\}$.

At the two boundaries $y = y_i$ ($i = 0, 1$), we define the Z_2 boundary conditions, namely, the odd boundary condition: $\Phi(x^\mu, y_i - y) = -\Phi(x^\mu, y_i + y)$ and the even boundary condition: $\Phi(x^\mu, y_i - y) = +\Phi(x^\mu, y_i + y)$, when Φ is the gauge boson or the ghost. For fermions $\psi = \Psi, \Lambda$, we should write Z_2 boundary conditions as

$$\psi(x^\mu, y_i - y) = \pm \eta_\psi \gamma_5 \psi(x^\mu, y_i + y), \tag{18}$$

where $\eta_\psi^2 = 1$. For the KK mode functions $f_{\Phi,n}(y) \equiv f_{\Phi,n}(e^{\sigma(y)})$, the odd boundary conditions can be written as

$$f_{\Phi,n}(y)\big|_{y_i} = 0 \quad (i = 0, 1), \tag{19}$$

whereas even boundary conditions take the form of [36, 40]:

$$\left(\frac{df_{\Phi,n}(y)}{dy} + r_\Phi \sigma'(y) f_{\Phi,n}(y)\right)\bigg|_{y=y_i} = 0 \quad (i = 0, 1), \tag{20}$$

where $r_\Phi = 1$, 2 and $\pm c$ for $\Phi = A_\mu$, A_y and $\psi_{R,L}$, respectively. It would be convenient [34] to rescale the KK mode functions (17) and to define

$$\check{f}_{\Phi,n}(z) \;\equiv\; z^{\check{\alpha}_\Phi}\left[A_{\Phi,n} J_{\check{\alpha}_\Phi}(\hat{m}_{\Phi,n} z) + B_{\Phi,n} Y_{\check{\alpha}_\Phi}(\hat{m}_{\Phi,n} z)\right] \tag{21}$$

where $\check{\alpha}_\Phi = 1, 0,$ and $1/2 \pm c$ for $\Phi = A_\mu$, A_z/z and $\psi_{R,L}$, respectively.[4] With (21), we can rewrite even boundary conditions (20) into the form of $\partial_z \check{f}_\Phi(z) = 0$.

In this model, the extra-dimensional components of the gauge field A_y can develop a non-zero vacuum expectation value (VEV) $\langle A_y \rangle$. Furthermore, since the non-simply connected topology of the extra dimension of the RS space-time, we cannot gauge away the Wilson-line phase : $\exp(ig\int_{y_0}^{y_1} dy \langle A_y \rangle)$. This phase can change the boundary condition and therefore can change mass spectrum of fields due to Aharonov-Bohm effect [47]. To see this, in the following we will consider one of the simplest but non-trivial case. In the beginning, we turned off gauge VEV and impose a Z_2 boundary condition on the theory. It is

$$\tilde{A}_\mu(x, -y + y_i) = +\tilde{P}_i \tilde{A}_\mu \tilde{P}_i^\dagger, \quad \tilde{A}_y(x, -y + y_i) = -\tilde{P}_i \tilde{A}_y \tilde{P}_i^\dagger, \tag{22}$$

here $\tilde{P}_0 = \tilde{P}_1 = \sigma_3$. This boundary conditions (22) arrows for $\tilde{A}_\mu^3$ and $\tilde{A}_y^{1,2}$ to have zero modes. Therefore this boundary condition break the $SU(2)$ gauge symmetry to $U(1)_3$ with massless gauge boson $\tilde{A}_\mu^{(3)}$. Due to the non-simply connected nature of S^1/Z_2 topology of the extra dimension of the RS space-time, $\tilde{A}_y^{(1,2)}$ can develop a VEV. Without loss of generality, we can set $\langle \tilde{A}_y \rangle$ in the direction of $A_y^{(2)}$. As a zero-mode solution of (14), we set gauge VEV as

$$\langle \tilde{A}_z(z) \rangle \;=\; vz\sigma_2, \tag{23}$$

---

[4] We choose $\eta_\psi = +1$ for ψ.

where v is a constant parameter. The $U(1)_3$ gauge symmetry can be broken, if $v \neq 0$ and if the Wilson line phase $\langle W \rangle = \exp(i \int_{z_0}^{z_1} g \langle \tilde{A}_z \rangle dz)$ does not commute with the generator of the $U(1)_3 : \sigma_3/2$. In the following we refer the gauge which is represented by non-zero VEV (23) and Z_2 boundary condition (22), as the "Aharonov-Bohm gauge" or the AB-gauge.

By using a gauge transformation

$$\begin{aligned} \tilde{A}_M \ \rightarrow \ A_M &= \tilde{\Omega} \tilde{A}_M \tilde{\Omega}^\dagger - \frac{i}{g} \tilde{\Omega} \partial_M \tilde{\Omega}^\dagger, && (24) \\ \tilde{\Omega}(z) \ &= \ \exp\left[-ig \int_{z_0}^{z} d\zeta \langle \tilde{A}_z(\zeta) \rangle \right] = \exp\left[-i \frac{gv}{2} (z^2 - z_0^2) \sigma_2 \right], && (25) \end{aligned}$$

we move to an another gauge $\langle A_z \rangle = 0$. The boundary condition of the gauge fields $\tilde{P}_i$ are also changed to P_i:

$$P_0 = \tilde{P}_0 = \sigma_3, \quad P_1 = e^{i\theta\sigma_2} \sigma_3 e^{-i\theta\sigma_2}, \tag{26}$$

by the gauge transformation: $P_i = \tilde{\Omega}(z_i) \tilde{P}_i \tilde{\Omega}^\dagger(z_i)$. In Eq.(26), θ are given by

$$\theta = \frac{gv}{2} \left(z_1^2 - z_0^2 \right). \tag{27}$$

Thus we find that in this gauge the gauge field $A_M^{(1,3)}$ obey the twisted boundary condition (26) at $z = z_1$, whereas the Wilson-line phase becomes trivial $\langle W \rangle = 1$. We refer the gauge with vanishing gauge VEV and with the boundary condition (26) as the (twisted) boundary condition gauge or the BC-gauge.

In the analogous way, we can set boundary conditions and perform gauge transformations of fermions. We can write the boundary conditions of Ψ and Λ in the AB-gauge as[5]

$$\tilde{\Psi}(-y + y_i) = \eta_\Psi \tilde{P}_i \tilde{\Psi}(+y + y_i), \quad \tilde{\Lambda}(-y + y_i) = \eta_\Lambda \tilde{P}_i \tilde{\Lambda}(+y + y_i) \tilde{P}_i^\dagger, \tag{28}$$

with $\eta_{\Psi,\Lambda}^2 = 1$. For simplicity, hereafter we set $\eta_\Psi = \eta_\Lambda = +1$.

In the BC gauge, since the gauge VEV $\langle A_z \rangle$ vanishes, we can solve the wave equations (13)(14)(15)(16) for $\Psi^{(i=1,2)}$, $A_M^{(i=1,3)}$ and $\Lambda^{(i=1,3)}$. As an example, we consider the right-handed fundamental fermion $\Psi_R^{(1,2)}$ with bulk mass c. In the BC gauge, wave functions take the form of

$$f_{R,n}^{(i)}(z) = z^{1/2} \left\{ a_n^{(i)} J_{c+1/2}(\hat{m}_n z) + b_n^{(i)} Y_{c+1/2}(\hat{m}_n z) \right\} \quad (i = 1, 2), \tag{29}$$

---

[5] For simplicity, we assume that all boundary conditions take same form as gauge field, nevertheless the boundary conditions of all fermions are not necessarily the same as the gauge fields.

where a_n and b_n are constant, and we set $\hat{m}_n^{(1)} = \hat{m}_n^{(2)} \equiv \hat{m}_n$. By solving twisted boundary condition in BC gauge (or by going back to AB gauge by gauge transformation $\Psi \to \tilde{\Psi} = \Omega\Psi$, with $\Omega = (\tilde{\Omega})^{-1}$ and considering the even (odd) boundary condition of $f_R^{(1)}$ ($f_R^{(2)}$) at $z = z_{0,1}$), we obtain conditions:

$$\begin{aligned}
(-a^{(1)}\sin\theta + a^{(2)}\cos\theta)J_{c+1/2}(\hat{m}_n z_i) + (-b^{(1)}\sin\theta + b^{(2)}\cos\theta)Y_{c+1/2}(\hat{m}_n z_i) &= 0, \\
(a^{(1)}\cos\theta + a^{(2)}\sin\theta)J_{c-1/2}(\hat{m}_n z_i) + (b^{(1)}\cos\theta + a^{(2)}\sin\theta)Y_{c-1/2}(\hat{m}_n z_i) &= 0, \\
&\quad (i = 0, 1).
\end{aligned} \tag{30}$$

In the same way we can write the boundary condition of $\Psi_L^{(1,2)}$, $A_M^{(1,3)}$ and $\Lambda_{L,R}^{(1,3)}$. These boundary condition can be written in the form of

$$M_\Phi(\hat{m})V_\Phi \;=\; 0, \tag{31}$$

where $V_\Phi = (a_\Phi^{(3)}, b_\Phi^{(3)}, a_\Phi^{(1)}, b_\Phi^{(1)})$ for $\Phi = A_M^{(3,1)}, \Lambda_{L,R}^{(3,1)}$, and $V_\Phi = (a_\Phi^{(1)}, b_\Phi^{(1)}, a_\Phi^{(2)}, b_\Phi^{(2)})$ for $\Phi = \Psi_{L,R}^{(1,2)}$. The matrix M_Φ is defined by

$$M_\Phi(\hat{m}) \;=\; \begin{pmatrix}
-s_1 J_\alpha(\hat{m}z_1) & -s_1 Y_\alpha(\hat{m}z_1) & c_1 J_\alpha(\hat{m}z_1) & c_1 Y_\alpha(\hat{m}z_1) \\
-s_0 J_\alpha(\hat{m}z_0) & -s_0 Y_\alpha(\hat{m}z_0) & c_0 J_\alpha(\hat{m}z_0) & c_0 Y_\alpha(\hat{m}z_0) \\
c_1 J_{\alpha-1}(\hat{m}z_1) & c_1 Y_{\alpha-1}(\hat{m}z_1) & s_1 J_{\alpha-1}(\hat{m}z_1) & s_1 Y_{\alpha-1}(\hat{m}z_1) \\
c_0 J_{\alpha-1}(\hat{m}z_0) & c_0 Y_{\alpha-1}(\hat{m}z_0) & s_0 J_{\alpha-1}(\hat{m}z_0) & s_0 Y_{\alpha-1}(\hat{m}z_0)
\end{pmatrix}, \tag{32}$$

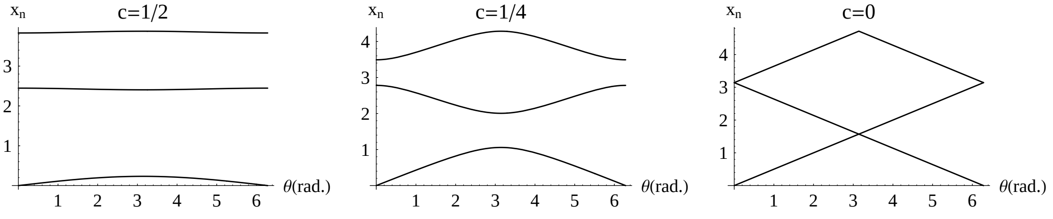
where $\alpha = 1, 0, c + 1/2$ and $c - 1/2$ for A_μ, A_z, ψ_R and ψ_L ($\eta_\psi = +1$), respectively. s_i and c_i are defined by

$$s_i(c_i) = \sin(\cos)\left(\frac{n_\Phi\theta}{2}\frac{z_i^2 - z_0^2}{z_1^2 - z_0^2} + \delta_\Phi\right), \tag{33}$$

where $\delta_\Phi = 0$ for $\Phi = A_\mu, \Psi_R, \Lambda_R$, and $\delta_\Phi = -\pi/2$ for $\Phi = A_z, \Psi_L, \Lambda_L$. The factor n_Φ depends on Φ's representation of the gauge group. In $SU(2)$ case, $n_\Phi = 1\,(2)$ when Φ is in fundamental (adjoint) representation. The n-th Kaluza-Klein state of the field Φ has a mass $m_{\Phi,n} = k\hat{m}_{\Phi,n}$, where the $\hat{m}_{\Phi,n}$ are defined as a n-th smallest solution of the equation: $\det M_\Phi(\hat{m}) = 0$. Defining

$$\begin{aligned}
N(\theta, \hat{m}, \alpha) \;\equiv\; & \frac{2\cos(n_\Phi\theta)}{\pi^2} \\
& + \frac{1}{2}\hat{m}^2 z_1 (F_{\alpha,\alpha-1}(\hat{m}, z_1)F_{\alpha-1,\alpha}(\hat{m}, z_1) + F_{\alpha,\alpha}(\hat{m}, z_1)F_{\alpha-1,\alpha-1}(\hat{m}, z_1))
\end{aligned} \tag{34}$$

FIG. 1: Plot of $x_{n=1,2,3}(\frac{1}{2}+c,\theta)$ (see text), for various θ and for $|c|=1/2$ (left), $|c|=1/4$ (center) and $|c|=0$ (right) with fixed $kR=12$. The n-th zero x_n of $N(\theta,x/z_1,\frac{1}{2}+c)$ corresponds to the n-th KK-mass m_n by the relation $m_n=kx_n/z_1$.



(where $F_{\alpha,\beta}(\hat{m},z)\equiv J_\alpha(\hat{m}z)Y_\beta(\hat{m})-J_\beta(\hat{m})Y_\alpha(\hat{m}z)$), we rewrite the condition $\det M_\Phi(\hat{m})=0$ as

$$N(n_\Phi\theta,\hat{m},\alpha_\Phi)=0, \tag{35}$$

where α_Φ and n_Φ are given by

$$\begin{array}{lcc} \hline\hline \Phi & \alpha_\Phi & n_\Phi \\ \hline A_M^{(1\leftrightarrow 3)} & 1 & 2 \\ A_M^{(2)} & 1 & 0 \\ \Psi^{(1\leftrightarrow 2)} & \frac{1}{2}+c_\Psi & 1 \\ \Lambda^{(1\leftrightarrow 3)} & \frac{1}{2}+c_\Lambda & 2 \\ \Lambda^{(2)} & \frac{1}{2}+c_\Lambda & 0 \\ \hline\hline \end{array}\ . \tag{36}$$

Let $x_n(\alpha,\theta)$ be the n-th smallest non-negative zeros of $N(\theta,x/z_1,\alpha)$. Thus, the n-th Kaluza-Klein mass of the field Φ : $m_{\Phi,n}$ is given by

$$m_{\Phi,n}=(k/z_1)\cdot x_n(\alpha_\Phi,n_\Phi\theta). \tag{37}$$

In FIG. 1 we plot $x_i(\frac{1}{2}+c,\theta)$ $(i=1,2,3)$ which are first three smallest zeros of $N(\theta,x/z_1,\frac{1}{2}+c)$ with $kR=12$. We see that the mass spectrum largely depends on θ when $|c|$ is small, whereas the dependence on θ become smaller for larger $|c|$ (here we note that $N(\theta,x,\alpha)$ has a symmetry $N(\theta,x,\alpha)=N(\theta,x,1-\alpha)$, as shown in Appendix B of [34]).[6] From the dependence of $x_n(\alpha,\theta)$ as we have seen above, we can expect that the the effective potential, which is obtained by summing up all of the Kaluza-Klein mode, has large (small) dependence on θ when $|c|$ is small (large).

---

[6] FIG. 1 of the present paper and FIG. 1 in [34] are similar to each other, although in each figure different parameters are changed ($|c|$ in the former and kR in the latter.)

We evaluate the 1-loop effective potential in a similar way as [28]. As an example we calculate the one-loop contribution of a fundamental fermion Ψ. This is given by

$$-4I = -4 \cdot \frac{-\mu^{4-d}}{2} \int \frac{d^d p}{i(2\pi)^d} \sum_n \log(-p^2 + m_n^2), \tag{38}$$

where d defined as $d = 4 - \epsilon$, μ is the renormalization scale, and m_n is the n-th positive-real solution of $N(\theta, m/k, \frac{1}{2} + c_\Psi) = 0$. The coefficient -4 reflects the four degrees of freedom of a Dirac fermion and the minus sign for the fermion loop. After performing the dimensional regularization, we can write I as

$$I = \frac{\mu^\epsilon}{2} \cdot \frac{\Gamma(-2 + \epsilon/2)}{(4\pi)^{2-\epsilon/2}} \sum_n m_n^{4-\epsilon}. \tag{39}$$

Here the summation $\sum_n m_n^{-s}$ can be rewritten as a contour integral:

$$\sum_n m_n^{-s} = \frac{k^{-s}}{2\pi i} \oint_C dz\, z^{-s} \frac{N'(\theta, z, \frac{1}{2} + c_\Psi)}{N(\theta, z, \frac{1}{2} + c_\Psi)}, \tag{40}$$

where the path C is a set of all circles surrounding each zeros of $N(\theta, z, \frac{1}{2}+c_\Psi)$ on the positive real axis. The contour integral in (40) can be calculated in a similar way to [30, 31, 46]. We find that θ-dependent part of I is finite.

$$I = \frac{1}{32\pi^2} \left(\frac{k}{z_1}\right)^4 v(\theta, \tfrac{1}{2} + c_\Psi) + (\theta\text{-independent}), \tag{41}$$

where $v(\theta, \nu)$ is defined by

$$\begin{aligned} v(\theta,\nu) \equiv \int_0^\infty dx\, x^3 \log\Bigg[& 1 + \frac{1}{2}\left(\frac{I_\nu(ax)K_{\nu-1}(x)}{I_{\nu-1}(x)K_\nu(ax)} - \frac{I_\nu(ax)K_\nu(x)}{I_\nu(x)K_\nu(ax)} \right. \\ & \left. - \frac{I_{\nu-1}(ax)K_{\nu-1}(x)}{I_{\nu-1}(x)K_{\nu-1}(ax)} + \frac{I_{\nu-1}(ax)K_\nu(x)}{I_\nu(x)K_{\nu-1}(ax)} \right) \\ & + \frac{I_{\nu-1}(ax)I_\nu(ax)K_{\nu-1}(x)K_\nu(x)}{I_{\nu-1}(x)I_\nu(x)K_{\nu-1}(ax)K_\nu(ax)} - \frac{\cos\theta}{2ax^2 I_{\nu-1}(x)I_\nu(x)K_{\nu-1}(ax)K_\nu(ax)} \Bigg], \end{aligned} \tag{42}$$

with $a \equiv 1/z_1$. This function $v(\theta, \nu)$ has a symmetry $v(\theta, \nu) = v(\theta, 1-\nu)$, and a periodicity $V(\theta, \nu) = v(\theta + 2\pi, \nu)$. The function (42) with $\nu = 1$ becomes the same form as the integral in Eq. (18) of [31]. Furthermore, when $\nu = 1/2$ we can rewrite $v(\theta, 1/2)$ as

$$\begin{aligned} v(\theta, 1/2) &= \left(\frac{1}{1-a}\right)^4 \int_0^\infty dt\, t^3 \log\left[1 - \frac{\cos\theta}{\cosh 2t}\right] + (\theta\text{-independent}) \\ &= (1-a)^{-4} \left\{ -\tfrac{3}{4}\mathrm{Re}\left[\mathrm{Li}_5(e^{i\theta})\right] - \tfrac{45}{2048}\zeta(5) \right\} + (\theta\text{-independent}), \end{aligned} \tag{43}$$

FIG. 2: Plot of $v(\theta, 1/2 + c)$ with $|c| = 0.0$(thin solid), $|c| = 0.4$(dashed) and $|c| = 0.5$(thick solid).

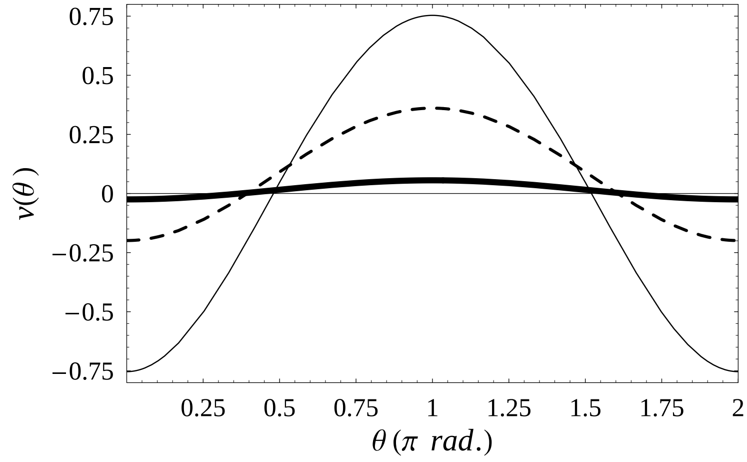


FIG. 3: Plot of $\Delta v(1/2 + c) \equiv v(\pi, 1/2 + c) - v(0, 1/2 + c)$ with $a = \exp(-12\pi)$.

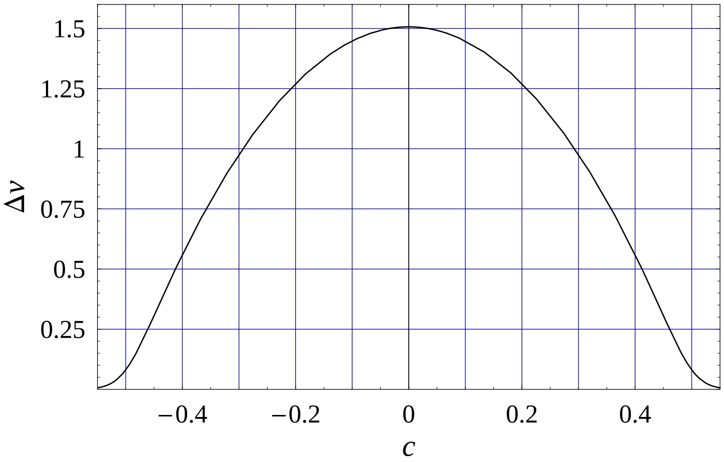
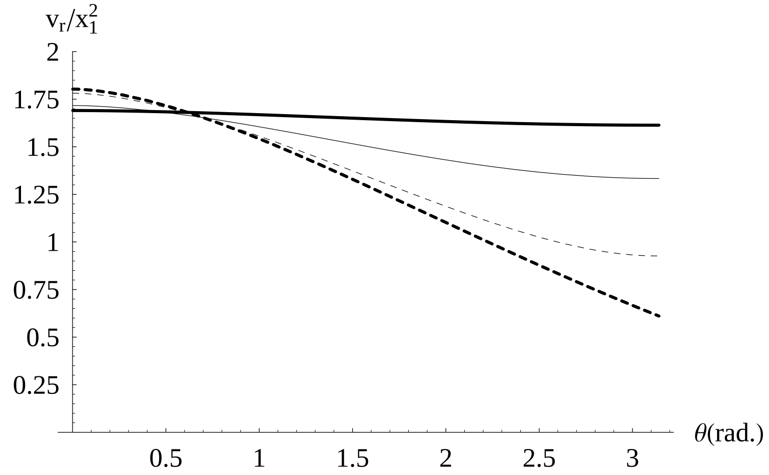


where $\mathrm{Li}_d(x)$ is the polylogarithm and $\zeta(x)$ is the Riemann zeta function. $\mathrm{Re}\,\mathrm{Li}_d(e^{i\theta})$ can be expanded as $\mathrm{Re}\,\mathrm{Li}_d(e^{i\theta}) = \sum_{n=1}^{\infty} \cos n\theta/n^d$, or expanded as $\mathrm{Re}\,\mathrm{Li}_5(e^{ix}) = \zeta(5) - \frac{1}{2}\zeta(3)x^2 + \left(\frac{25}{288} - \frac{1}{24}\log x\right)x^4 + \mathcal{O}(x^6)$. The expression (43) coincides with the result obtained in Sec. IV of Ref. [30]. The shapes of $v(\theta, \nu)$ with respect to θ with different ν are similar with each other (FIG. 2). We show dependence of amplitude $\Delta v(\frac{1}{2} + c) \equiv v(\pi, \frac{1}{2} + c) - v(0, \frac{1}{2} + c)$ on c in FIG. 3. In the case of flat extra dimension it is known [10, 18] that the contribution to one-loop effective potential from a field dumps when the bulk mass of the field is much larger compared to (the inverse of) the size of the extra dimension. It is also true for the models in the RS space-time. However, in the RS space-time the relation between the effective potential and the 4-dimensional mass of the field is different from the case of flat extra dimension. Therefore a fermion with the large lowest KK mass can have a

FIG. 4: The ratio $v_r(\theta, c)/(x_1(\frac{1}{2} - c, \theta))^2$ (see text) with $kR = 12$, for $c = 0.5$ (thick solid), 0.4 (thin solid), 0.2 (thin dashed) and 0.0 (thick dashed), respectively.



large contribution to the effective potential. To see this, let us see the relation between the magnitude of the effective potential and the mass of the fermion at the lowest KK level. The lowest KK mass $m(c_\Psi)$ of a $SU(2)$ fundamental fermion with bulk mass c_Ψ is given by $m(c_\Psi) = (k/z_1) \cdot x_1(\frac{1}{2} \pm c_\Psi, \theta)$. And we define the magnitude of the one-loop effective potential from the fermion as $v_r(\theta, c) \equiv v(\theta, c) - v(0, c)$. In FIG. 4, we show the relation between $v_r(\theta, c)$ and the square of $x_1(\frac{1}{2} - c, \theta)$. From FIG. 4, it can be safely said that the magnitude of the one-loop contribution to the effective potential is proportional to the square of the lowest KK mass of the fermion when the absolute value of bulk mass of the fermion is sufficiently large. This means that when the fermion's lowest-KK mass is small (large) the contribution of the fermion to the effective potential is small (large).

Now we are ready to discuss the gauge symmetry breaking by Wilson line phase. The effective potential of the $SU(2)$ model consists of gauge and ghost loop contribution $V_{\rm gh}$, contribution from the fundamental fermion Ψ $V_{\rm fd}$ and/or in adjoint fermion Λ: $V_{\rm ad}$. They are given by (θ-independent part is omitted.),

$$\begin{aligned} V_{\rm gh}(\theta) &= 3\mathcal{C} \cdot v(2\theta, 1), \\ V_{\rm fd}(\theta, c_\Psi) &= -4\mathcal{C} \cdot v(\theta, \tfrac{1}{2} + c_\Psi), \\ V_{\rm ad}(\theta, c_\Lambda) &= -4\mathcal{C} \cdot v(2\theta, \tfrac{1}{2} + c_\Lambda), \end{aligned} \tag{44}$$

where $\mathcal{C} \equiv (k/z_1)^4/32\pi^2$. In the AB gauge, the $SU(2)$ gauge symmetry is at first broken by the boundary conditions $\tilde{P}_{0,1}$. The generator $T^{(3)}$ commutes with both of the boundary conditions and becomes the generator of the $U(1)_3$ gauge symmetry. When the Wilson-line phase becomes non-trivial and does not commutes with $T^{(3)}$, the remaining $U(1)_3$ gauge symmetry could be broken. The Wilson-line phase is determined dynamically as a configuration which minimize the effective potential. As a first example, we consider the model in which the gauge field and a fundamental fermion is included. The effective potential in this case can be written as $V_{\rm gh}(\theta) + V_{\rm fd}(\theta, c_\Psi)$. This potential has a global minimum at $\theta = \pi$ $(0 \leq \theta \leq \pi)$ for any value of c_Ψ. When $\theta = \pi$, the $U(1)_3$ gauge symmetry remains unbroken because the Wilson-line phase $\langle W(\theta = \pi)\rangle = \exp[i\pi\sigma_2] = {\rm diag}(-1, -1)$ can commute with the $U(1)_3$ generator $T^{(3)}$. As a next example, we consider the model in which the gauge field and an adjoint fermion with bulk mass c_Λ are included. We can write the effective potential as $V_{\rm gh}(\theta) + V_{\rm ad}(\theta, c_\Lambda)$. This has global minima at $\theta = 0, \pi$ $(0 \leq \theta \leq \pi)$ for $|c_\Lambda| > 0.507$, and has a global minimum at $\theta = \theta^{\rm min} \sim \pi/2$ for $|c_\Lambda| < 0.507$. In the latter case the the non-trivial Wilson line $\langle W(\theta^{\rm min})\rangle \sim \exp[i(\pi/2)\sigma_2] = i\sigma_1$ cannot commute with $T^{(3)}$. Thus the $U(1)_3$ gauge symmetry can be broken by the Wilson line, as seen in the case of flat-extra dimension [6, 27]. And the pattern of the symmetry-breaking depends on the bulk mass of the fermion, as seen in [18] in the case of the flat extra dimension.

III. SU(3) MODELS

In this section we consider models with the $SU(3)_w$ gauge symmetry in the RS as an extension of electroweak theory.

A. $SU(3)_w$ model

In this model, the electroweak $SU(2) \times U(1)$ gauge symmetry is enlarged to the $SU(3)_w$ gauge symmetry. We define generators of $SU(3)_w$ as $T^a \equiv \lambda_a/2$ $(a = 1, ..., 8)$, where λ_a are the Gell-Mann matrices. We also define $T^9 \equiv \lambda_9/2$ and $T^{10} \equiv \lambda_{10}/2$ ($\lambda_9 \equiv {\rm diag}(0, 1, -1)$ and $\lambda_{10} \equiv {\rm diag}(-2, 1, 1)/\sqrt{3}$) as generators of $U(1)_9$ and $U(1)_{10}$ gauge symmetries, respectively. Following the way in [15, 16, 17, 34], we introduce $SU(3)_w$-triplet fermions, namely "quarks" $\Psi_{\rm fd=u,c,t}$, and "leptons" $\Psi_{{\rm fd=e},\mu,\tau}$:

$$\Psi^{(c=1,2,3)}_{\rm u(c,t)} = ({\rm d(s,b)}_l,\ {\rm u(c,t)}_l,\ {\rm u(c,t)}_r)^T, \quad \Psi_{{\rm e}(\mu,\tau)} = (\nu_{{\rm e}(\mu,\tau),l},\ {\rm e}(\mu,\tau)_l,\ {\rm e}(\mu,\tau)_r)^T, \tag{45}$$

where the superscript (c) denotes the $SU(3)_{\rm color}$-charge. For simplicity, we introduce the bulk mass terms of $\Psi_{\rm fd}$ fields in the diagonal form, i.e., the mass terms for fermions in the action is given by

$$S_{\Psi,\mathrm{mass}} = -\sum_{\mathrm{fd}} \int d^4x \int dy |E| c_{\mathrm{fd}} \epsilon(y) k \bar{\Psi}_{\mathrm{fd}} \Psi_{\mathrm{fd}}, \tag{46}$$

in $SU(3)_w$ gauge basis. c_{fd} is the bulk mass parameter of the fermion Ψ_{fd}. If the mass matrix is not diagonal, various phenomena of the flavor-mixing will be observed [45].

In order to break the $SU(3)_w$ to the "electroweak" $SU(2) \times U(1)$ symmetry, and to obtain chiral fermion zero modes, we chose the orbifold boundary condition in the AB-gauge as

$$\tilde{P}_i = \mathrm{diag}(-1, -1, +1) \quad (i = 0, 1). \tag{47}$$

When we turn off the gauge VEV $\langle A_z \rangle = 0$, the $SU(3)_w$ symmetry is broken to $SU(2)_w \times U(1)_8$ only by the boundary condition (47), where the unbroken generators of $SU(2)_w$ and $U(1)_8$ are $T^{(1,2,3)}$ and $T^{(8)}$, respectively. Gauge fields $A_\mu^{(1,2,3,8)}$ and $A_z^{(4,5,6,7)}$ have massless modes. Zero modes of the fermions $\Psi_{\mathrm{u},0}$ and $\Psi_{\mathrm{e},0}$ are given by[7]

$$\Psi_{\mathrm{u},0} = (\mathrm{d}^{\mathrm{C}}_{l,L},\, \mathrm{u}^{\mathrm{C}}_{l,L},\, \mathrm{u}^{\mathrm{C}}_{r,R})^T, \quad \Psi_{\mathrm{e},0} = (\nu_{l,L},\, \mathrm{e}_{l,L},\, \mathrm{e}_{r,R})^T, \tag{48}$$

where the superscript C denotes the charge conjugation (here we omitted indices for the color charge). The zero modes of $A_z^{(4,5,6,7)}$ can develop a VEV. Here we assume that A_z develops a VEV in the direction of λ_7. In the AB-gauge, we set

$$\langle \tilde{A}_z \rangle = \frac{2\theta_H}{g} \frac{z}{z_1^2 - z_0^2} \begin{pmatrix} & & \\ & & -i \\ & i & \end{pmatrix}, \tag{49}$$

where θ_H is the Wilson-line phase parameter which will be determined dynamically. Once the gauge VEV is turned on : $\theta_H \neq 0$, the $SU(2)_w$ symmetry is broken, and "up type quarks" $\mathrm{u}, \mathrm{c}, \mathrm{t}$ and "charged leptons" e, μ, τ get each mass terms through the gauge coupling, i.e., $\bar{\Psi}_u g \tilde{A}_z^{(7)} \Psi_u$. We can move to the BC-gauge by the singular gauge transformation with

---

[7] We choose $\eta_\Psi = +1$.

$\Omega = \exp(i\theta_H \lambda_7)$. This gauge transformation reads

$$\begin{pmatrix} \tilde{A}^{(1)}_M - i\tilde{A}^{(2)}_M \\ \tilde{A}^{(4)}_M - i\tilde{A}^{(5)}_M \end{pmatrix} = \begin{pmatrix} \cos\theta_H & \sin\theta_H \\ -\sin\theta_H & \cos\theta_H \end{pmatrix} \begin{pmatrix} A^{(1)}_M - iA^{(2)}_M \\ A^{(4)}_M - iA^{(5)}_M \end{pmatrix}, \tag{50}$$

$$\begin{pmatrix} \tilde{A}^{(9)}_M \\ \tilde{A}^{(6)}_M \end{pmatrix} = \begin{pmatrix} \cos 2\theta_H & \sin 2\theta_H \\ -\sin 2\theta_H & \cos 2\theta_H \end{pmatrix} \begin{pmatrix} A^{(9)}_M \\ A^{(6)}_M \end{pmatrix}, \tag{51}$$

$$\begin{pmatrix} \tilde{\Psi}^{(2)} \\ \tilde{\Psi}^{(3)} \end{pmatrix} = \begin{pmatrix} \cos\theta_H & \sin\theta_H \\ -\sin\theta_H & \cos\theta_H \end{pmatrix} \begin{pmatrix} \Psi^{(2)} \\ \Psi^{(3)} \end{pmatrix}, \tag{52}$$

Thus under the gauge transformation Ω, $A^{(1,4)}_M$, $A^{(2,5)}_M$ and $\Psi^{(2,3)}$ transform like a $SU(2)$ fundamental field respectively, whereas $A^{(9,6)}_M$ transforms like $SU(2)$ adjoint field in the previous section. Each pair of the gauge field zero modes $(A^{(i)}_{\mu,0}, A^{(j)}_{z,0})$ $((i,j) = (1,4), (2,5), (9,6)))$ and fermion zero modes $(\Psi^{(2)}_{\mathrm{fd},L,0}, \Psi^{(3)}_{\mathrm{fd},R,0})$ can obtain mass terms through the gauge coupling. We define these massive field as $A^{(1\leftrightarrow 4)}_M$, $A^{(2\leftrightarrow 5)}_M$, $A^{(6\leftrightarrow 9)}_M$ and $\Psi^{(2\leftrightarrow 3)}$, respectively. Zero modes of $A^{(10)}_\mu$, $A^{(7)}_z$ and $\Psi^{(1)}_{\mathrm{fd},0,L}$ remain massless. Especially, $A^{(10)}_{\mu,0}$ and $A^{(7)}_z$ are identified with the $U(1)_{10}$ gauge field ("photon") and one of the $SU(2)_w$-doublet "Higgs", respectively. These fields are massless at tree level.

The n-th KK masses $m_{\Phi,n}$ of a field Φ are given by $m_{\Phi,n} = (k/z_1) \cdot x_n(\alpha_\Phi, n_\Phi \theta_H)$, where α_Φ and n_Φ for a field Φ are summarized in (53).

Φ	α_Φ	n_Φ
$A^{(1\leftrightarrow 4, 2\leftrightarrow 5)}_M$	1	1
$A^{(6\leftrightarrow 9)}_M$	1	2
$A^{(7,10)}_M$	1	0
$\Psi^{(2\leftrightarrow 3)}_{\mathrm{fd}}$	$\frac{1}{2} + c_{\mathrm{fd}}$	1
$\Psi^{(1)}_{\mathrm{fd}}$	$\frac{1}{2} + c_{\mathrm{fd}}$	0

(53)

Now we discuss about the fermion masses in the 4-dimensional effective theory. We define the function of the lowest KK mass of a field Φ $\mu(\alpha_\Phi, \theta_H, n_\Phi)$ as

$$\mu(\alpha_\Phi, \theta_H, n_\Phi) \equiv \frac{k}{z_1} x_1(\alpha_\Phi, n_\Phi \theta_H). \tag{54}$$

As pointed out in [34], it is useful to write the mass of the fields in unit of the W-boson mass m_W. We rewrite $\mu(\alpha, theta, n))$ as

$$\mu_W(\alpha_\Phi, \theta_H, n_\Phi) \equiv m_W \cdot \frac{\mu(\alpha_\Phi, \theta_H, n_\Phi)}{\mu(1, \theta_H, 1)} = m_W \cdot \frac{x_1(\alpha_\Phi, n_\Phi \theta_H)}{x_1(1, \theta_H)}, \tag{55}$$

here we have used $m_W = \mu(1, \theta_H, 1)$. With these quantity we can write the lowest KK-mass of fields. For example, masses of “quark” and “lepton” $m_{\rm fd=u,c,t,e,\mu,\tau}$ can be written as $m_{\rm fd} = \mu_W(\frac{1}{2} + c_{\rm fd}, \theta_H, 1)$.

If the mass of a field is sufficiently smaller than $m_{KK} \equiv \pi k/(z_1 - 1)$, we can utilize approximation formulas in Appendix A. For $kR = 12$, $\pi m_W/m_{KK} \approx x_1(1, \theta) \gtrsim 0.2326$. In the region $0 \leq \theta_H \leq \pi$, m_{KK} is a monotonically decreasing function of θ_H, and we find the lower bound :

$$m_{KK} \geq m_{KK}(\theta_H = \pi) \simeq 1086 \text{GeV}. \tag{56}$$

Since quark and lepton masses are all sufficiently smaller than m_{KK}'s lower bound (56), we can use approximation formulas in Appendix A to rewrite the mass of a fundamental fermion with bulk mass $c_{\rm fd}$. It is written in the form of

$$m_{\rm fd} \simeq \bar{\mu}_W(\tfrac{1}{2} + c_{\rm fd}, \theta_H, 1) = m_W \sqrt{\frac{z_1(c_{\rm fd} + \frac{1}{2})(c_{\rm fd} - \frac{1}{2})kR\pi}{2\sinh[(c_{\rm fd} + \frac{1}{2})kR\pi]\sinh[(c_{\rm fd} - \frac{1}{2})kR\pi]}}. \tag{57}$$

We see from (57) that masses of “quarks” and “leptons” are almost independent of θ_H. Therefore we can find values of bulk mass $c_{\rm fd}$ for each “quarks” and “leptons” from its 4D mass irrespective of the value of θ_H which is obtained by solving the Wilson-line dynamics. Thus, from the formula (57), we obtain bulk masses of “top quark” $c_{\rm top}$ and other “quarks” and “leptons” [34]. We obtain $c_{\rm top} \simeq 0.4366$ and $|c_{\rm u,c,e,\mu,\tau}| > 0.6$, respectively. In the way similar to [15, 16, 17] but extended for the warped space-time, we obtain the effective potential:

$$\begin{aligned} V_{\rm eff}^{\rm gh+t} &= V_{\rm gauge} + V_{\rm top}, & (58)\\ V_{\rm gauge} &= +3\mathcal{C} \cdot \left[2v(\theta_H, 1) + v(2\theta_H, 1)\right], & (59)\\ V_{\rm top} &= -3 \cdot 4\mathcal{C} \cdot v(\theta_H, \tfrac{1}{2} + c_{\rm top}), & (60) \end{aligned}$$

where we have neglected contributions from other quarks and leptons, because they have small contributions to the effective potential with their large bulk masses. The factor 3 in $V_{\rm top}$ reflects the degrees of freedom of $SU(3)_{\rm color}$-color charge. The effective potential $V_{\rm eff}^{\rm gh+t}$ has the global minimum at $\theta_H = \pi$. The Wilson-line phase with $\theta_H = \pi$ (in AB-gauge) is

$$\langle W(\theta_H = \pi)\rangle = \exp\left[i\pi\lambda_7\right] = \text{diag}(1, -1, -1), \tag{61}$$

and it can commute with both of boundary condition $\tilde{P}_{0,1}$ and with both of two $U(1)$ generators $T^{(10)}$ and $T^{(9)}$ simultaneously. Hence the $SU(2)_w \times U(1)_8$ symmetry is broken to $U(1)_9 \times U(1)_{10}$. Besides the "electro-magnetic" $U(1)_{10}$, one extra $U(1)_9$ symmetry remains unbroken.

When the effective potential $V_{\rm eff}(\theta_H)$ has the global minimum at $\theta_H = \theta_H^{\rm min}$, the one-loop Higgs mass m_h is written in terms of m_W as

$$m_h \simeq m_W \frac{kR}{4} \sqrt{\pi \alpha_W V_{\rm eff}^{(2)}(\theta_H^{\rm min})/\mathcal{C}} \left| \csc \frac{\theta_H^{\rm min}}{2} \right| , \tag{62}$$

where α_W is 4D fine-structure constant of $SU(2)$ before the symmetry breaking[8], and $V_{\rm eff}^{(2)}(\theta_H^{\rm min}) \equiv \partial^2 V_{\rm eff}(\theta_H)/\partial \theta_H^2|_{\theta_H = \theta_H^{\rm min}}$. By substituting $m_W = 80.4\,\text{GeV}$, $\alpha_W = 0.032$, $V_{\rm eff} = V_{\rm eff}^{\rm gh+t}$ and $\theta_H^{\rm min} = \pi$ into (62), we obtain $m_h \simeq 119.7\text{GeV}$. This value is slightly larger than the lower-bound $m_h \geq 114\text{GeV}$ from the LEP experiment [48].

B. $SU(3)$ model with an adjoint fermion

In this subsection, we add an $SU(3)_w$ adjoint fermion Λ into the model to break unwanted $U(1)_9$ symmetry.[9] When we turn off the gauge VEV in the AB-gauge, the Z_2 boundary conditions $\tilde{\Lambda}(y_i - y) = \gamma_5 \tilde{P}_i \tilde{\Lambda}(y_i + y) \tilde{P}_i^\dagger$ with $\tilde{P}_{i=0,1}$ defined in (47). This boundary condition projects out the half of the zero mode of $\Lambda^{(1-8)}$, and leaves the four left- and four right-handed massless fermions. Once we turn on the gauge VEV in the direction of λ_7, pairs of left-handed and right-handed fermions $(\Lambda_R^{(1)}, \Lambda_L^{(4)})$, $(\Lambda_R^{(2)}, \Lambda_L^{(5)})$, $(\Lambda_L^{(6)}, \Lambda_R^{(9)})$, and pairs with opposite chiralities (e.g. $(\Lambda_L^{(1)}, \Lambda_R^{(4)})$) yields massive fermions: $\Lambda^{(1\leftrightarrow 4)}$, $\Lambda^{(2\leftrightarrow 5)}$ and $\Lambda^{(6\leftrightarrow 9)}$, respectively. The n-th KK mass the field $\Phi = \Lambda^{(i)}$ is given by $m_{\Phi,n} = (k/z_1) x_n(\alpha_\Phi, n_\Phi \theta_H)$, where α_Φ and n_Φ are

Φ	α_Φ	n_Φ
$\Lambda^{(1\leftrightarrow 4, 2\leftrightarrow 5)}$	$\frac{1}{2} + c_{\rm ad}$	1
$\Lambda^{(9\leftrightarrow 6)}$	$\frac{1}{2} + c_{\rm ad}$	2
$\Lambda^{(7,10)}$	$\frac{1}{2} + c_{\rm ad}$	0

---

[8] The 4-dimensional coupling is given by $g_4^2 = g^2/\pi R$.

[9] One of another way to break the symmetry is to assign quarks and leptons into larger representations of $SU(3)_w$, as discussed in [24].

with $c_{\rm ad}$ being the bulk mass parameter of the adjoint fermion Λ. With these values we obtain the contribution to the effective potential from the adjoint fermion, which is given by

$$V_{\rm adjoint}(c_{\rm ad},\theta_H) \ = \ -4\mathcal{C}\cdot\left[v(2\theta_H,\tfrac{1}{2}+c_{\rm ad})+2v(\theta_H,\tfrac{1}{2}+c_{\rm ad})\right]. \tag{64}$$

Hence the total effective potential is given by

$$V^{\rm gh+t+ad}_{\rm eff}(c_{\rm ad},\theta_H)\equiv V_{\rm gh}(\theta_H)+V_{\rm top}(\theta_H)+V_{\rm adjoint}(c_{\rm ad},\theta_H)). \tag{65}$$

In FIG. 5, shapes of $\Delta v_{\rm eff}(c_{\rm ad},\theta_H)\equiv\left[V^{\rm gh+t+ad}_{\rm eff}(c_{\rm ad},\theta_H)-V^{\rm gh+t+ad}_{\rm eff}(c_{\rm ad},\pi)\right]$ for various $c_{\rm ad}$ are shown. When $|c_{\rm ad}|\lesssim 0.413$, the effective potential has a minimum at $\theta_H=\theta_H^{\rm min}$ where $0<\theta_H^{\rm min}<\pi$. The Wilson-line phase $\langle W\rangle=\exp(i\theta_H^{\rm min}\lambda_7)$ cannot commute with T^9 if $0<\theta_H^{\rm min}<\pi$. Therefore the $U(1)_9$ gauge symmetry is broken and we obtain the breaking : $SU(2)_w\times U(1)_8\to U(1)_{10}$. When the bulk mass of the adjoint fermion becomes large: $|c_{\rm ad}|\gtrsim 0.413$, the contribution from adjoint fermion $V_{\rm adjoint}$ becomes negligible. Thus the effective potential has the global minimum at $\theta_H=\pi$ and the $U(1)_9$ remains unbroken, as we have seen in the previous subsection.

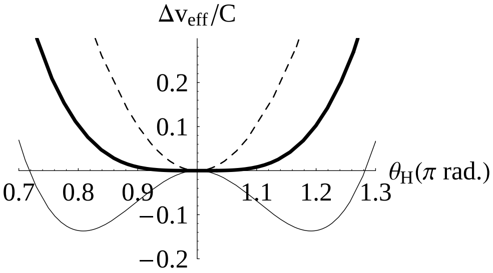

FIG. 5: The plot of $\Delta v_{\rm eff}(c_{\rm ad},\theta_H)/\mathcal{C}$ (see text), for $c_{\rm ad}=0.50$ (dashed), 0.413 (thick solid) and 0.35 (thin solid).

When $U(1)_9$ is broken, the massive "Z-boson" should be identified with lowest KK mode of $A_\mu^{(6\leftrightarrow 9)}$. The Z-boson mass m_Z is given by

$$m_Z=\mu_W(1,\theta_H,2)\simeq\bar{\mu}_W(1,\theta_H,2)=m_W|\sin(\theta_H)\csc(\theta_H/2)|. \tag{66}$$

The ratio m_Z/m_W depends on the Wilson-line phase θ_H and, is a monotonically-decreasing function of θ_H for $0\leq\theta_H\leq\pi$, and vanishes when $\theta_H=\pi$. The massless gauge boson which appears when $\theta_H=\pi$ is the gauge boson $A_\mu^{(9)}$ of $U(1)_9$ symmetry. At the limit $\theta_H\to 0$, m_Z

and m_W satisfy a relation $m_Z = 2m_W$. This relation can be seen in the case of flat extra dimension [1, 19, 20]. In the case of the warped extra dimension with $kR > 0$, m_Z (m_W) dependence on θ_H is $m_Z \propto \sin\theta_H$ ($m_W \propto \sin\theta_H/2$), whereas in flat dimension $m_Z \propto 2\theta_H$ and $m_W \propto \theta_H$. When $k \to 0$, the small correction to the approximation in Eq. (66) becomes no longer negligible. Thus we can expect that in the small k limit the ratio m_Z/m_W approaches to one in the case of flat extra dimension. We should note that the change of m_Z/m_W occurs at tree level by varying θ_H, unlike the radiative correction to the T-parameter.

Now we estimate the lowest KK-masses of fermions $\Lambda^{(i\leftrightarrow j)}$, $(i,j) = (1,4), (2,5), (6,9)$: $m_{\rm ad}^{i\leftrightarrow j}$. Recalling Eqs. (A2) and (A3), we obtain $m_{\rm ad}^{(1\leftrightarrow 4)} = m_{\rm ad}^{(2\leftrightarrow 5)} = \mu_W(\frac{1}{2}+c_{\rm ad}, \theta_H, 1) \equiv m_{\rm ad1}$ and $m_{\rm ad}^{(6\leftrightarrow 9)} = \mu_W(\frac{1}{2} + c_{\rm ad}, \theta_H, 2) \equiv m_{\rm ad2}$. We should note that a relation $m_{\rm ad1}/m_{\rm ad2} \simeq m_Z/m_W$ holds as long as all $m_{{\rm ad1,ad2},Z,W}$ are sufficiently smaller than m_{KK}. Two massless fermions with opposite chirality: $\Lambda_{L,0}^{(7)}$ and $\Lambda_{R,0}^{(10)}$ remain at tree level. As an another physical quantity we can obtain the n-th Kaluza-Klein photon $m_{\gamma,n}$ mass which is given by $m_{\gamma,n} = (k/z_1)x_n^{(0)}$, where $x_n^{(\alpha)}$ is the n-th smallest positive solution of $F_{\alpha,\alpha}(1/z_1, x) = 0$ and $x_1^{(0)} \simeq 2.4466$.

In this model, by fixing values of unknown parameters kR and $c_{\rm ad}$, the global minimum of the effective potential is determined and we can obtain the value of $\theta_H^{\rm min}$ at which the effective potential has the global minimum. From $c_{\rm ad}$ and $\theta_H^{\rm min}$ (and effective potential (65)), we can calculate 1-loop Higgs mass m_h and tree level masses of vector bosons m_W, m_Z and of adjoint fermions $m_{\rm ad1,ad2}$, 1st KK-photon mass $m_{\gamma,1}$, and the KK scale m_{KK}. In TABLE. I, we have summarized these masses for specific values of $|c_{\rm ad}| \leq 0.4$. In FIG. 6, we have shown the masses $m_{\rm ad1}$, $m_{\rm ad2}$, m_Z, and m_h for $|c_{\rm ad}| \geq 0.38$ with $kR = 12$, $\alpha_W = 0.032$ and $m_W = 80.4$ GeV. In the region $|c_{\rm ad}| \lesssim 0.413$, all of these masses are monotonically decreasing function of $|c_{\rm ad}|$. When $|c_{\rm ad}| \gtrsim 0.413$, we obtain $\theta_H^{\rm min} = \pi$. Thus $m_{\rm ad2}$ and m_Z vanish in this region. The mass of the Higgs also decreases with increasing $|c|$ for larger $|c_{\rm ad}|$ as long as $|c_{\rm ad}| \lesssim 0.413$. For $|c_{\rm ad}| \gtrsim 0.413$, however, the mass of Higgs increases and closes to ~ 120GeV, because the contribution from the top quark becomes dominant in this region.

So that $m_W = 80.4$ GeV and $m_Z = 91.2$ GeV satisfy the relation (66), $\theta_H^{\rm min} \simeq 0.616\pi$ is required. This value of $\theta_H^{\rm min}$ is, however, smaller than the lower bound $\theta_H^{\rm min} \gtrsim 0.733\pi$ which is obtained by solving Wilson-line dynamics. Furthermore, it seems unlikely to push up (down) the m_Z ($\theta_H^{\rm min}$) just by introducing more adjoint fermions, because the minimum of

TABLE I: The Wilson-line phase $\theta_H^{\rm min}$ at which the effective potential has the global minimum, the mass of Higgs at 1-loop order, tree level masses of Z-boson, adjoint fermions $m_{\rm ad1}$,$m_{\rm ad2}$, KK scale m_{KK}, and 1st Kaluza-Klein mass of the photon $m_{\gamma,1}$, for various bulk mass $c_{\rm ad}$ of the adjoint fermion, with $kR = 12.0$, $\alpha_W = 0.0320$ and $m_W = 80.4$ GeV as given parameters.

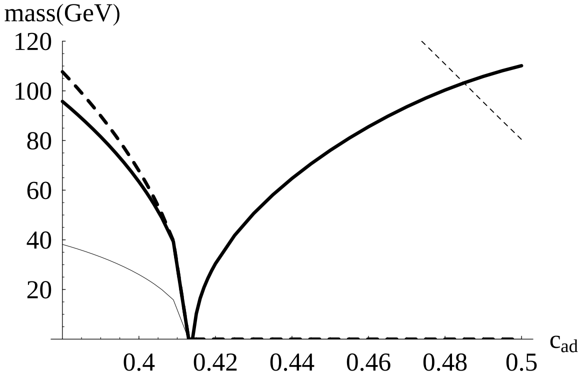
FIG. 6: Plots of $m_{\rm ad1}$ (thin dashed at the upper-right corner), $m_{\rm ad2}$ (thick dashed), m_Z (thin solid) and m_h (thick solid) for $c_{\rm ad}$: $0.45 \leq |c_{\rm ad}| \leq 0.55$, with $kR = 12.0$ and $\alpha_W = 0.032$.



the $V_{\rm adjoint}(\theta_H)$ locates at $\theta_H \sim 0.689\pi$ and we cannot make $\theta_H^{\rm min}$ smaller than 0.689π only by introducing more adjoint fermion into the model. In the following subsections we try to push up (down) m_Z ($\theta_H^{\rm min}$), by adding some scalar fields or twisted fermions.

C. Adding Scalar Fields

The action of a bulk scalar field S can be written as [40]

$$\mathcal{L}_s \;=\; \int d^4x \int_{-\pi R}^{\pi R} dy\, \sqrt{|G|}\left\{(D_M S)^\dagger (D^M S) - (s_S k^2 + t_S \sigma'') S^\dagger S\right\}, \tag{67}$$

where s_S and t_S are the bulk and boundary mass of the scalar field S, respectively.[10] When s_S and t_S satisfy the relation:

$$2 - t_S = \sqrt{4 + s_S} = \nu, \tag{68}$$

the KK-mass spectrum of such scalar becomes identical to a fermion field with the bulk mass $c = \pm(\nu - 1/2)$, and the contribution to the effective potential par degrees of freedom turns out to be just same magnitude but with opposite sign as the one from the fermion in the same representation of $SU(3)_w$. Hereafter we consider the case where boundary- and bulk-masses of scalar fields satisfy the condition (68).

Now we propose a way to lift up (put down) the Z-boson mass ($\theta_H^{\rm min}$) by introducing scalar fields into the model. We add one or more scalar fields $S_f^a (f = 1, \ldots, N_s,\, a = 1, 2, 3)$, which are in the fundamental representation of $SU(3)_w$, into the model. The contribution to the effective potential from such scalar fields is given as

$$V_{\rm scalar} = +2\mathcal{C} \sum_{f=1}^{N_s} v(\tfrac{1}{2} + b_f, \theta_H), \tag{69}$$

where b_f $(f = 1, \ldots, N_s)$ are mass parameters of the scalar S_f^a and related with the boundary and bulk mass parameters t_{S_f}, s_{S_f} by $t_{S_f} = b_f \mp 3/2$ and $s_{S_f} = b_f^2 \pm b_f - 15/4$. The total effective potential is given by $V_{\rm eff}^{\rm gh+t+ad+s} \equiv V_{\rm eff}^{\rm gh+t+ad} + V_{\rm scalar}$. For simplicity, we use an approximation of Eq. (69), which is given by

$$V_{\rm scalar} \simeq -\xi \cdot \mathcal{C} \cdot {\rm Re}\, {\rm Li}_5(e^{i\theta}), \tag{70}$$

where we have introduced a dimensionless parameter $\xi = \xi(b_f)$, $0 \le \xi \lesssim \frac{3}{2} N_s$. Since $V_{\rm scalar}(\theta_H)$ has the global minimum at $\theta_H = 0$, we can shift the location of the minimum $\theta_H^{\rm min}$

---

[10] For simplicity, we do not include scalar quartic terms. Therefore, we do not consider the case in which the scalar fields develop VEVs and cause Higgs mechanism here. The cases in which the Higgs mechanism and the dynamical gauge-Higgs unification coexist are discussed in [49].

FIG. 7: The dependence of $\theta_H^{\min}$ as the minimum of $V_{\rm eff}^{\rm gh+t+ad+s}$ on the scalar contribution ξ, for $c_{\rm ad} = 0.0$ (thick solid), 0.3 (thin solid), 0.4 (thin dashed) and 0.45 (thick dashed). FIG.7-(b) is a close-up view of 7-(a). In both (a) and (b), the solid horizontal line shows $\theta_H = 0.616\pi$.

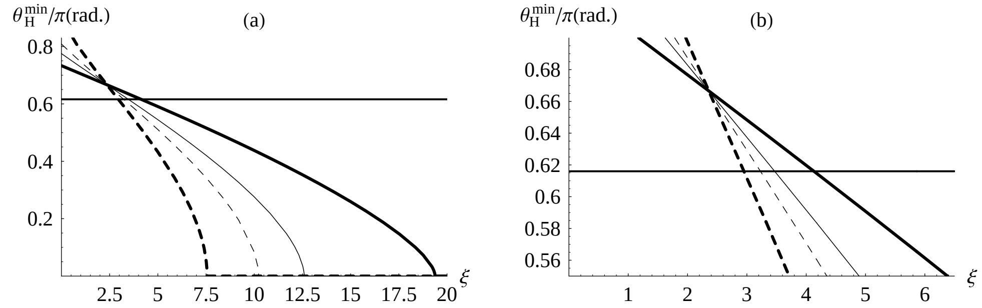


TABLE II: Mass spectrum of $SU(3)_w$ models with an adjoint fermion and scalar fields which makes $\theta_H = \theta_H^c \equiv 0.616\pi$.

$\lvert c_{\rm ad}\rvert$	0.0	0.1	0.2	0.3	0.35	0.4
ξ^c	4.13	4.06	3.84	3.47	3.23	2.95
$m_h(c_{\rm ad}, \theta_H^c, \xi^c)$[GeV]	291	285	266	231	205	169
$m_{\rm ad1}(c_{\rm ad}, \theta_H^c)$ [GeV]	349	342	320	279	249	209
$m_{\rm ad2}(c_{\rm ad}, \theta_H^c)$ [GeV]	396	388	363	317	283	238

of $V_{\rm eff}^{\rm gh+t+ad+s}$ to 0 by increasing the value of ξ. Thus in this model we can change the ratio m_Z/m_W by tuning adjoint fermion mass $c_{\rm ad}$ and the scalar field contribution parameterized by ξ. In FIG. 7(a) and (b), we have shown how $\theta_H^{\min}$ depends on ξ. FIG. 7 tells that $\theta_H^{\min} \simeq 0.616\pi$ can be achieved by tuning ξ for any value of $c_{\rm ad}$. Thus for a given value of $c_{\rm ad}$, we can define $\xi^c = \xi^c(c_{\rm ad})$ such that $V_{\rm eff}^{\rm gh+t+ad+s}$ has the global minimum at $\theta_H = 0.616\pi$ with $\xi = \xi^c$. In TABLE. II, we summarized the value of ξ^c for each value of $c_{\rm ad}$. And we re-calculate masses m_h, $m_{\rm ad1,2}$ with ξ^c and $\theta_H^{\min} = 0.616\pi$. The KK-scale m_{KK} and the first KK-photon mass at $\theta_H = 0.616\pi$ are 1331GeV and 1037GeV, respectively.

One may wonder why the Higgs mass becomes larger nevertheless scalar field may cancel the fermion's contribution. The reason can be explained as follows. First, we remember that $V_{\rm adjoint}(\theta_H)$ and $V_{\rm scalar}(\theta_H)$ have similar shape to $\cos 2\theta_H$ and $-\cos\theta_H$, respectively. Then the contribution of the adjoint fermion to the Higgs mass (i.e. the curvature of $V_{\rm adjoint}(\theta_H)$) has the maximum around at $\theta_H \sim \pi/2$, whereas one of fundamental scalars vanishes at

$\theta_H \sim \pi/2$. Thus the Higgs mass becomes small when the θ_H closes to $\pi/2$.

D. Twisted Fermion

An alternative way to shift the Z-boson mass in the $SU(3)_w$ model is to introduce one or more "twisted fermions" $\psi_{\rm tw}$, which boundary condition is twisted even in AB-gauge. As an example, we consider the case where $\psi_{\rm tw}$ is in the fundamental representation of $SU(3)_w$. As a possible boundary condition of $\psi_{\rm tw}$ in the AB-gauge, we define

$$\tilde{\psi}_{\rm tw}(x, y_i + y) = \eta_{\rm tw}\gamma_5 \tilde{P}_{tw,i}\tilde{\psi}(x, y_i - y) \quad (i = 0, 1), \tag{71}$$

$$\tilde{P}_{tw,0} = \tilde{P}_0, \quad \tilde{P}_{tw,1} = \exp(i\varphi\lambda_7)\tilde{P}_1 \exp(-i\varphi\lambda_7), \tag{72}$$

where $\tilde{P}_i$ is defined in (47) and $\eta_{\rm tw} = \pm 1$. When we introduce N_t copies of such twisted-fermions $\psi^i_{\rm tw}$ $(i = 1, ..., N_t)$ with $\varphi = \pi$ into the model, the contribution to the one-loop effective potential induced from such fermions is given by

$$V_{\rm tw} = -4\mathcal{C}\sum_{i=1}^{N_t} v(\tfrac{1}{2} + c^i_{\rm tw}, \theta_H + \pi), \tag{73}$$

where $c^i_{\rm tw}$ is the bulk mass parameter of $\psi^i_{\rm tw}$. Since $v(\nu, \theta + \pi) \approx -v(\nu, \theta)$, we can make use of the result of Sec. III C by replacing $V_{\rm scalar}$ in (70) with $V_{\rm tw}$ and $N_s/2$ with N_t.

IV. SUMMARY AND COMMENTS

In the present paper, we investigated the dynamical gauge-Higgs unification in the RS space-time. In Sec. II we consider the SU(2) gauge theory in the RS space-time. We calculate one-loop effective potential with respect to the Wilson-line phase. Especially we clarified the contribution from a fermion with the bulk mass parameter c. The obtained effective potential properly inter/extrapolates the results which are known for $|c| = 0$, $1/2$. We see that the gauge symmetry can be broken by dynamically-induced Wilson line when we introduce an adjoint fermion into the model and that the breaking pattern of the gauge symmetry depends on the bulk mass of the adjoint fermion.

In Sec.III we consider $SU(3)_w$ gauge models in the RS as toy models of 5D extensions of the electroweak theory. We found that it is possible to break $SU(2) \times U(1)$ to $U(1)$ by introducing an adjoint fermion. The large mass hierarchy among quarks and leptons are naturally obtained by adjusting their bulk mass parameters of the order of unity. We calculate one-loop Higgs mass numerically. In the $SU(3)_w$ model the Higgs mass can be changed from zero to $\sim 290\,\mathrm{GeV}$ with $kR = 12.0$. We have also estimated mass spectrum of this model for various value of mass of the adjoint fermion, which are determined by the RS parameter kR and bulk mass parameter of the adjoint fermion. Interestingly, these predicted masses of Higgs and new fermions are in the range where LHC experiment can explore. In this model, we see that the ratio of W-boson mass to the Z-boson mass varies with respect to the Wilson-line phase. This occurs at tree level. We find the way to tune the ratio m_Z/m_W to satisfy the realistic one $\sim 91.2/80.4$, by introducing $SU(3)_w$ fundamental scalar fields with the bulk and boundary mass terms which satisfy the relation (68), or fermions with twisted boundary condition. Unfortunately, the $SU(3)_w$ model still has some problems, e.g., varying m_Z/m_W may occur due to the lack of custodial symmetry in this model, some SM and non-SM fermions remain massless, and quarks and leptons cannot have correct isospin and hypercharge simultaneously. To obtain a more realistic model of the EWGHU in the RS space-time, the choice of the enhanced electroweak symmetry and the assignment of matter contents should be reconsidered.

We have seen that in the $SU(3)_w$ model a quark with small bulk masses has a heavy lowest KK state[11], and that such heavy fermions have large contribution to the effective potential of Higgs because of the smallness of bulk masses. The converse is also true; fermions with large bulk mass term have light lowest KK masses and have small contributions to the effective potential. It remind us the qualitative similarity with the CW mechanism; In CW mechanism the contribution to the Higgs potential from a heavy quark loop is large because a heavy fermion has large Yukawa coupling to the Higgs field. However, we have to note that in the dynamical gauge-Higgs unification the quadratic divergence of Higgs mass is absent, thanks to the gauge symmetry in the higher-dimensional space-time.

APPENDIX A: APPROXIMATION FORMULAS

When the 4D (or lowest KK mode) mass of a field Φ is sufficiently smaller than m_{KK}, i.e., $\pi^2 m_{\Phi,0}^2 \ll m_{KK}^2$, we can use an approximation formula for $m_{\Phi,0}$, as discussed in [34]. The mass $m_{\Phi,0}$ is approximated by

$$m_{\Phi,0} = \bar{\mu}(\alpha_\Phi, \theta_H, n_\Phi) \left\{ 1 + \mathcal{O}\left(\frac{\bar{\mu}^2 \pi^2}{m_{KK}^2} \right) \right\}, \tag{A1}$$

where $\bar{\mu}(\alpha, \theta, n)$ is defined by

$$\bar{\mu}(\alpha, \theta_H, n) \;\equiv\; k \sqrt{\frac{\alpha(\alpha-1)}{z_1 \sinh[\alpha k \pi R] \sinh[(\alpha-1) k \pi R]}} \cdot \left| \sin \frac{n\theta_H}{2} \right|. \tag{A2}$$

The mass of the weak boson m_W is give by $m_W = \mu(1, \theta_H, 1)$, and can be approximated by[12]

$$m_W = \frac{m_{KK}}{\pi} \sqrt{\frac{2}{k\pi R}} \cdot \left| \sin \frac{\theta_H}{2} \right| \left\{ 1 + \mathcal{O}\left(\frac{m_W^2 \pi^2}{m_{KK}^2} \right) \right\}. \tag{A3}$$

From Eqs. (A2),(A3), the lowest KK mass $m_{\Phi,0}$ is also approximated (in terms of m_W) by

$$m_{\Phi,0} = \bar{\mu}_W(\alpha_\Phi, \theta_H, n_\Phi) \left\{ 1 + \mathcal{O}(m_{\Phi,0}^2 \pi^2 / m_{KK}^2) \right\}, \tag{A4}$$

where $\bar{\mu}_W$ is defined by

$$\begin{aligned} \bar{\mu}_W(\alpha, \theta_H, n) \;&\equiv\; m_W \frac{\bar{\mu}(\alpha, \theta_H, n)}{\bar{\mu}(1, \theta, 1)} \\ &=\; m_W \sqrt{\frac{z_1 \alpha(\alpha-1) k R \pi}{2 \sinh[\alpha k R \pi] \sinh[(\alpha-1) k R \pi]}} \cdot \left| \sin \frac{n\theta_H}{2} \csc \frac{\theta_H}{2} \right|. \end{aligned} \tag{A5}$$

Here we should note that $\bar{\mu}_W(\alpha, \theta_H, 1)$ is independent of the θ_H.

As for m_{KK}, by using W-mass formula (A3) inversely we obtain

$$m_{KK} \simeq \pi m_W \sqrt{\pi k R / 2}\, \left| \csc(\theta_H/2) \right|. \tag{A6}$$

We should also note that Eq. (A2) is an approximation of $\mu(\alpha, \theta_H, n)$ and valid valid only when $\bar{\mu} \ll m_{KK}$. When α close to $1/2$, the difference between $\mu(\alpha, \theta_H, n)$ and $\bar{\mu}(\alpha, \theta_H, n)$ becomes large (see FIG. 8).

---

[12] Here we have taken the limit: $\lim_{\alpha \to 1} \bar{\mu}(1, \theta_H, 1)$.

FIG. 8: $\mu_W(\frac{1}{2}-c,\theta_H,1)$ and $\bar{\mu}_W(\frac{1}{2}-c,\theta_H,1)$ with fixed $m_W = 80.4$GeV and $kR = 12$ and various c are plotted. From the top, the thick solid, thick dashed, thin dashed and thin solid curve [horizontal line] show $\mu_W(\frac{1}{2}-c,\theta_H,1)$ $[\bar{\mu}_W(\frac{1}{2}-c,\theta_H,1)]$ for $c = 0.0, 0.3, 0.4$ and 0.45, respectively. The lowest single horizontal line indicates $m_W = 80.4$GeV.
